DSA

I. Objectives

Introduction

Depth-First Search (DFS)

- Explores as far as possible along each branch before backtracking
- Uses stack data structure (either explicitly or via recursion)
- Time Complexity: O(V + E)
- Space Complexity: O(V)

Breadth-First Search (BFS)

- Explores all neighbors at current depth before moving deeper
- Uses queue data structure
- Time Complexity: O(V + E)
- Space Complexity: O(V)

This laboratory activity aims to implement the principles and techniques in:

- Understand and implement Depth-First Search (DFS) and Breadth-First Search (BFS) algorithms
- Compare the traversal order and behavior of both algorithms
- Analyze time and space complexity differences

II. Methods

- Copy and run the Python source codes.
- If there is an algorithm error/s, debug the source codes.
- Save these source codes to your GitHub.
- Show the output
- 1. Graph Implementation

```
from collections import deque import time
```

```
class Graph:
    def __init__(self):
        self.adj_list = {}

    def add_vertex(self, vertex):
        if vertex not in self.adj_list:
            self.adj_list[vertex] = []

    def add_edge(self, vertex1, vertex2, directed=False):
        self.add_vertex(vertex1)
        self.add_vertex(vertex2)

    self.adj_list[vertex1].append(vertex2)
    if not directed:
        self.adj_list[vertex2].append(vertex1)
```

```
def display(self):
     for vertex, neighbors in self.adj list.items():
       print(f"{vertex}: {neighbors}")
2. DFS Implementation
def dfs recursive(graph, start, visited=None, path=None):
  if visited is None:
     visited = set()
  if path is None:
     path = []
   visited.add(start)
   path.append(start)
  print(f"Visiting: {start}")
   for neighbor in graph.adj list[start]:
     if neighbor not in visited:
        dfs_recursive(graph, neighbor, visited, path)
  return path
def dfs iterative(graph, start):
   visited = set()
  stack = [start]
  path = []
  print("DFS Iterative Traversal:")
  while stack:
     vertex = stack.pop()
     if vertex not in visited:
        visited.add(vertex)
       path.append(vertex)
       print(f"Visiting: {vertex}")
       # Add neighbors in reverse order for same behavior as recursive
        for neighbor in reversed(graph.adj list[vertex]):
          if neighbor not in visited:
             stack.append(neighbor)
   return path
3. BFS Implementation
def bfs(graph, start):
   visited = set()
  queue = deque([start])
  path = []
  print("BFS Traversal:")
   while queue:
     vertex = queue.popleft()
     if vertex not in visited:
       visited.add(vertex)
       path.append(vertex)
       print(f"Visiting: {vertex}")
```

for neighbor in graph.adj_list[vertex]: if neighbor not in visited: queue.append(neighbor)

return path

Questions:

- 1 When would you prefer DFS over BFS and vice versa?
- 2 What is the space complexity difference between DFS and BFS?
- 3 How does the traversal order differ between DFS and BFS?
- 4 When does DFS recursive fail compared to DFS iterative?

III. Results

- 1 DFS is preferred when exploring all possible paths or checking connectivity in deep or large graphs, such as solving mazes or topological sorting. BFS is better when the goal is to find the shortest path or explore nodes level by level, such as in navigation or network routing.
- 2 DFS uses less memory because it goes deep one path at a time. BFS uses more since it stores many nodes in a queue.
- 3 DFS goes deep into one branch before moving to another, while BFS explores all nodes level by level. In short, DFS goes deep first; BFS goes wide first.
- 4 . Recursive DFS can fail on very large or deep graphs because it uses too many recursive calls, causing a stack overflow. Iterative DFS avoids this problem by using a manual stack instead of recursion.

IV. Conclusion

This activity showed how BFS and DFS work differently in graph traversal. BFS explores level by level, while DFS goes deep into each path. Both are useful for solving real-world problems like pathfinding and network analysis.
